

Brief Report – Rosacea vs Acne Classification Application

This project was developed to classify skin images as either Rosacea or Acne using a Convolutional Neural Network (CNN). The dataset was obtained from a publicly available source and divided into two classes for training. The trained TensorFlow/Keras model was deployed with Streamlit to allow users to upload a skin image and receive a prediction. Challenges included improving prediction accuracy and resolving deployment issues such as missing libraries. These challenges were solved through image preprocessing, data augmentation, and careful testing. Future improvements include expanding the dataset and supporting more skin conditions.
